Problem Set #8

Forward contracts. European call options. European put options.

8.1. Forwards.

Problem 8.1. (5 points) A soy-bean farmer shorts forward contracts on soy in an amount matching his crop volume and with delivery at harvest time. Then, he is considered:

- (a) an arbitrageur.
- (b) a broker.
- (c) a speculator.
- (d) a hedger.
- (e) None of the above.

Solution: (d)

8.2. Calls.

Problem 8.2. The initial price of a non-dividend-paying asset is \$100. A six-month, \$95-strike European call option is available at a \$8 premium.

The continuously compounded risk-free interest rate equals 0.04.

What is the break-even point for this call option?

- (a) 86.84
- (b) 87
- (c) 103
- (d) 103.16
- (e) None of the above.

Solution: (d)

We need to solve for s in

$$(s - 95)_+ = 8e^{0.02} \Rightarrow s = 95 + 8e^{0.02} = 103.16$$

Problem 8.3. (5 points) A stock's price today is \$1000 and the annual effective interest rate is given to be 5%. You write a one-year, \$1,050-strike call option for a premium of \$10 while you simultaneously buy the stock. What is your **profit** if the stock's spot price in one year equals \$1,200?

- (a) \$150.00
- (b) \$139.90
- (c) \$10.50
- (d) - \$39.00
- (e) None of the above.

Solution: (c)

$$S(T) - 1000(1.05) - (S(T) - K)_+ + 10(1.05) = 1050 - 990(1.05) = 10.50.$$

Problem 8.4. (20 points)

The primary ingredient for a certain jeweler is gold which she intends to buy in exactly one year. She considers all of her other production-related expenses to be negligible.

The jeweler uses exactly one ounce of gold to produce every one of her pieces, and will be able to sell every piece for \$1,000.

The jeweler models the market price of gold in one year as follows:

Gold price in one year	Probability
750 per ounce	0.2
850 per ounce	0.5
950 per ounce	0.3

The jeweler hedges the price of gold by buying a 1-year call option with an exercise price of \$900 per ounce. The option costs \$100 per ounce now.

The continuously compounded risk-free interest rate is 5%.

Calculate the expected profit of the **hedged** portfolio per piece of jewelry produced.

Solution:

With $S(T)$ denoting the market price of gold at time $T = 1$, the jeweler's **hedged** profit per piece of jewelry can be expressed as

$$1,000 - \min(S(T), 900) - 100e^{0.05} = 894.873 - \min(S(T), 900).$$

So, her expected **hedged** profit equals

$$894.873 - \mathbb{E}[\min(S(T), 900)] = 894.873 - (0.2 \cdot 750 + 0.5 \cdot 850 + 0.3 \cdot 900) = 49.873.$$

8.3. Puts.

Problem 8.5. The initial price of the market index is \$900. After 3 months the market index is priced at \$915. The nominal rate of interest convertible monthly is 4.8%. The premium on the put, with a strike price of \$930, is \$8.00. What is the profit at expiration for a **long** put?

- (a) \$15.00 loss
- (b) \$6.90 loss
- (c) \$6.90 gain
- (d) \$15.00 gain
- (e) None of the above.

Solution: (c)

The profit from a position is defined as the position's payoff minus the future value of the initial cost.

If $S(T) = 915$ denotes the price of the market index at time $T = 0.25$ (i.e., in three months), then the payoff of the long put is $(K - S(T))_+$, where $K = 930$ denotes the strike of the put. So, since $K > S(T)$, the payoff is

$$(930 - 915)_+ = 15.$$

The future value of the initial put premium is

$$8(1 + 0.004)^3 = 8.0964.$$

So, the profit is

$$15 - 8.0964 = 6.90.$$

Problem 8.6. Sample FM(DM) #12

Consider a European put option on a stock index without dividends, with 6 months to expiration, and a strike price of 1,000. Suppose that the nominal annual risk-free rate is 4% **convertible semiannually**, and that the put costs 74.20 now. What price must the index be in 6 months so that being long the put would produce the same profit as being short the put?

- A. 922.83
- B. 924.32
- C. 1,000.00
- D. 1,075.68
- E. 1,077.17

Solution: (b)

Method I. A quick and insightful way of solving this problem is by realizing that the long-put and the short-put profits are negatives of each other. So, the only way they can be equal is at the “break-even” point. We solve for s in

$$(K - s)_+ - V_P(0) \left(1 + \frac{i^{(2)}}{2}\right) = (1000 - s)_+ - 74.20(1.02) = 0.$$

The solution is $s = 924.32$.

Method II. This is the more pedestrian method. The long-put profit is

$$(K - s)_+ - V_P(0) \left(1 + \frac{i^{(2)}}{2}\right) = (1000 - s)_+ - 74.20(1.02).$$

The short-put profit is the exact negative of the expression above, i.e.,

$$-(K - s)_+ + V_P(0) \left(1 + \frac{i^{(2)}}{2}\right) = -(1000 - s)_+ + 74.20(1.02).$$

So, algebraically, we need to solve for s in the equation

$$\begin{aligned} (1000 - s)_+ - 74.20(1.02) &= -(1000 - s)_+ + 74.20(1.02) &\Leftrightarrow & 2(1000 - s)_+ = 2 \cdot 74.20(1.02) \\ &&\Leftrightarrow & (1000 - s)_+ = 74.20(1.02). \end{aligned}$$

We get the same answer as above, of course.

Problem 8.7. Farmer Shaun is producing sweet potatoes. He intends to harvest 10,000–cartons’ worth in six months. His total costs are \$12.00 per carton.

He wishes to hedge using European put options. There are two puts on sweet potatoes with the exercise date in six months available: one with the strike price of \$13 per carton and another with the strike price of \$15 per carton. Their premiums are \$0.15 and \$0.18, respectively.

Assume that the prevailing risk-free interest rate is 4% effective for the half-year period.

At harvest time, in six months, it turns out that the sweet-potato spot price equals \$14. What would Farmer Shaun’s profit be if he had decided to hedge using the \$13-strike put versus his profit if he had decided to use the \$15-strike put to hedge?

Solution: Farmer Shaun’s unhedged position has the following profit:

$$10,000(S(T) - 12)$$

where $S(T)$ stands for the spot price of sweet potatoes in six months.

If he decided to hedge using put options, he would **long** the put. So, the profit of the \$13-strike-put hedge would be:

$$10,000(13 - S(T))_+ - 10,000 \times 0.15 \times 1.04.$$

The profit of the \$15-strike-put hedge would be:

$$10,000(15 - S(T))_+ - 10,000 \times 0.18 \times 1.04.$$

The profit of the hedged position with the given $S(T) = 14$ in the first case equals

$$10,000(14 - 12 - 0.15 \times 1.04) = 18,440.$$

For the second insurance strategy, the profit is

$$10,000(14 - 12 + (15 - 14) - 0.18 \times 1.04) = 28,128.$$
