The maximum number of points on this exam is 65.

Problem 1.1. (15 points) The primary ingredient in the production of a certain instrument is one ounce of platinum. The platinum will be bought to complete the final phase of production in exactly one quarter year. The prices of other ingredients and cumulative labor costs aggregate to \$400 per unit. Upon completion, each unit can be sold for \$2000.

The market price of platinum in three months is modeled as follows:

$$\text{Platinum price per ounce} \sim \begin{cases} \$1,433.00 & \text{with probability } 0.1 \\ \$1,533.00 & \text{with probability } 0.6 \\ \$1,633.00 & \text{with probability } 0.3 \end{cases}$$

The buyer hedges the price of platinum by buying a three-month call option with an exercise price of \$1,500 per ounce. The option costs \$78 per ounce now.

The continuously compounded risk-free interest rate is 5%.

Calculate the expected profit per unit produced of the <u>**hedged**</u> position.

Solution: If $S(T)$ denotes the price of one ounce of platinum in three months, then the profit of the hedged portfolio can be expressed as

$$2000 - 400 - \min(S(T), 1500) - 78e^{0.05/4} = 1521.02 - \min(S(T), 1500).$$

So, the expected profit equals

$$1521.02 - (1433 \times 0.1 + 1500 \times 0.9) = 27.72$$

Problem 1.2. (10 points)The probability mass function p_X of a discrete random variable X is given by

$$p_X(x) = \begin{cases} 1/4, & \text{for } x = 10 \\ 2/3, & \text{for } x = 20 \\ 1/12, & \text{for } x = 40 \end{cases}$$

Find $\mathbb{E}[\max(X - 15, 0)]$.

Solution: The random variable $\max(X - 15, 0)$ has the following distribution

$$\max(X - 15, 0) \sim \begin{cases} 0 & \text{with probability } 1/4 \\ 5 & \text{with probability } 2/3 \\ 25 & \text{with probability } 1/12 \end{cases}$$

So, its expectation is

$$\mathbb{E}[\max(X - 15, 0)] = 5\left(\frac{2}{3}\right) + 25\left(\frac{1}{12}\right) = \frac{10}{3} + \frac{25}{12} = \frac{40 + 25}{12} = \frac{65}{12}.$$

.

Problem 1.3. (5 points) Here is some information about two forward contracts with delivery dates in one year:

	Current price of underlying	Forward price
Forward I	100	105
Forward II	90	92

Alfur enters a long position in Forward I and a short position in Forward II. It turns out that the final price of the underlying asset for Forward I equals \$102, while the final price of the underlying asset for Forward II equals \$89.

Let the continuously compounded, risk-free interest rate be 0.03.

What is Alfur's profit?

Solution: The initial cost of any forward contract is zero, so the profit and the payoff are equal. For the long Forward I, Alfur's payoff is

$$102 - 105 = -3.$$

For the short Forward II, Alfur's payoff is

$$92 - 89 = 3.$$

Alfur's overall profit is zero.

Problem 1.4. (5 points) Let the function f be given by

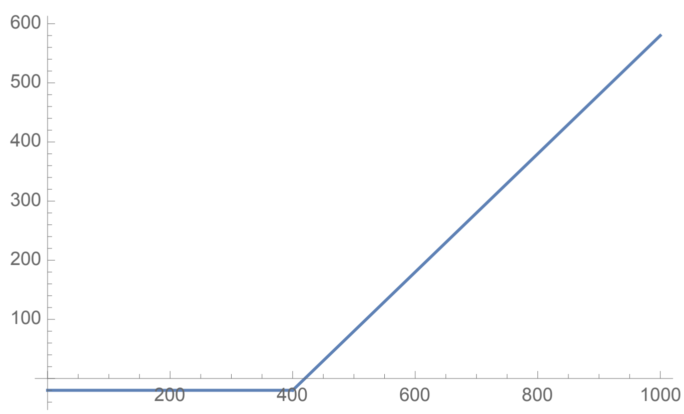
$$f(x) = \begin{cases} x - 400 & \text{for } x \geq 400 \\ 0 & \text{otherwise} \end{cases}$$

Draw the graph of the function g defined as

$$g(x) = f(x) - 20.$$

Carefully label your axes.

Solution:



Problem 1.5. (10 points) Let the function f be defined as

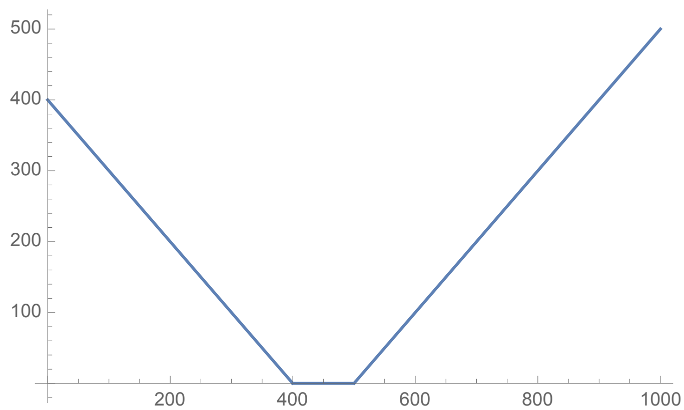
$$f(x) = \begin{cases} 400 - x & \text{for } x < 400 \\ 0 & \text{for } x \geq 400 \end{cases}$$

Let the function g be defined as

$$g(x) = \begin{cases} 0 & \text{for } x < 500 \\ x - 500 & \text{for } x \geq 500 \end{cases}$$

Draw the graph of the function $f + g$. Label your axes carefully.

Solution:



Problem 1.6. (10 points) Let the current price of a market index be \$80. Consider a European six-month, at-the-money call option on this market index.

We model the price of the market index in half a year as follows:

$$S(1/2) \sim \begin{cases} 78 & \text{with probability } 1/6 \\ 82 & \text{with probability } 1/2 \\ 84 & \text{with probability } 1/3 \end{cases}$$

What is the expected payoff of this call option?

Solution: Since the option is at-the-money, the strike price is \$80. We have

$$V_C(1/2) = (S(1/2) - 80)_+ \sim \begin{cases} 0 & \text{with probability } 1/6 \\ 2 & \text{with probability } 1/2 \\ 4 & \text{with probability } 1/3 \end{cases}$$

So,

$$\mathbb{E}[V_C(T)] = 2\left(\frac{1}{2}\right) + 4\left(\frac{1}{3}\right) = \frac{7}{3}.$$

Problem 1.7. (10 points) Let the current price of a non-dividend-paying stock be \$40. A market maker writes a \$38-strike, three-month call option on this stock. The option's price is \$2.72. The market-maker simultaneously buys one share of the underlying stock.

The continuously compounded, risk-free interest rate is 0.04.

For which final value of the stock price will the market maker break even?

Solution: The initial cost of the portfolio is $40 - 2.72 = 37.28$. This is a covered call, so the expression for the payoff is, in our usual notation,

$$-(S(T) - K)_+ + S(T) = \min(S(T), K).$$

In this problem, the payoff function for the portfolio is, therefore, $v(s) = min(s, 38)$. We need to solve for s in

$$\min(s, 38) - 37.28e^{0.04/4} = 0 \quad \Rightarrow \quad \min(s, 38) = 37.65467 \quad \Rightarrow \quad s = 37.65467.$$
