## Project #3

## Milica Cudina

## 2024-03-31

## Problem #1 (5+10+5+10+10+10+10+10+5+25=70 points)

Solve Problem 4.8.13 (pp. 192-193) from the textbook.

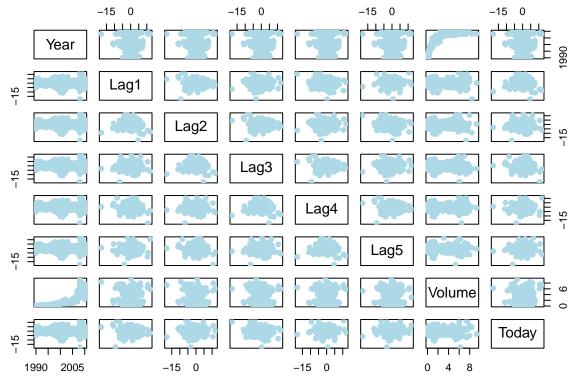

Hint: Here is a list of libraries you will need:

```
library(MASS)
library(ISLR2)
##
## Attaching package: 'ISLR2'
## The following object is masked from 'package:MASS':
##
## Boston
library(e1071)
library(class)
```

Solution: First, here is some exploratory data analysis.

```

plot(Weekly[, -9], pch=19, col="lightblue")
```

As time goes by, there is more and more trading. So, there is a nice correlation between Year and Volume. Other than that, I cannot discern a pattern.

```
mlr.fit <- glm(

##
## (Dispersion parameter for binomial family taken to be 1)
##
##
      Null deviance: 1496.2 on 1088 degrees of freedom
## Residual deviance: 1486.4 on 1082 degrees of freedom
## AIC: 1500.4
##
## Number of Fisher Scoring iterations: 4
```

Lag2 is the only significant one.

Now, it's time for the **confusion matrix**.

```
probs <- predict(mlr.fit, type = "response")</pre>
glm.pred=rep("Down", length(probs))
glm.pred[probs>0.5]<-"Up"
tab <- table(glm.pred, Weekly$Direction)</pre>
tab
##
## glm.pred Down Up
##
       Down
             54 48
       Uр
             430 557
sum(diag(tab))/sum(tab)
## [1] 0.5610652
mean(Weekly$Direction=="Up")
## [1] 0.555556
```

The prediction is correct a bit over 56% of the time. However, the proportion of the realized "Up"s was just under 56%. So, constantly saying "Up" would work almost as well as our logistic regression.

Now, for training and testing.

```
attach(Weekly)
train <- (Year< 2009)
test=Weekly[!train,]
Direction.test=Direction[!train]
dim(test)
## [1] 104
fit.tr <- glm(Direction ~ Lag2, data = Weekly, subset=train, family = binomial)
probs.tr <- predict(fit.tr, test[,-9], type = "response")</pre>
probs.tr

## [1] 104
tab <- table(glm.pred, Direction.test)</pre>
tab
##
          Direction.test
## glm.pred Down Up
              9 5
##
      Down
             34 56
      Uр
sum(diag(tab))/sum(tab)
## [1] 0.625
Using LDA, we get
lda.tr <- lda(Direction ~ Lag2, data = Weekly, subset=train)</pre>
lda.tr
## lda(Direction ~ Lag2, data = Weekly, subset = train)
## Prior probabilities of groups:
       Down
                   Up
## 0.4477157 0.5522843
##
## Group means:
              Lag2
```

```
## Down -0.03568254
       0.26036581
## Up
## Coefficients of linear discriminants:
              LD1
##
## Lag2 0.4414162
lda.pred <- predict(lda.tr, test[,-9], type = "response")$class</pre>
#length(lda.pred)
tab <- table(lda.pred, Direction.test)</pre>
tab
##
           Direction.test
## lda.pred Down Up
##
       Down
               9 5
       Uр
              34 56
sum(diag(tab))/sum(tab)
## [1] 0.625
```

For QDA implementation, we just change the command above.

```
qda.tr <- qda(Direction ~ Lag2, data = Weekly, subset=train)</pre>
qda.tr
## Call:
## qda(Direction ~ Lag2, data = Weekly, subset = train)
## Prior probabilities of groups:
        Down
## 0.4477157 0.5522843
## Group means:
## Down -0.03568254
         0.26036581
## Up
qda.pred <- predict(qda.tr, test[,-9], type = "response")$class</pre>
#length(lda.pred)
tab <- table(qda.pred, Direction.test)</pre>
tab
##
           Direction.test
## qda.pred Down Up
      Down
              0 0
              43 61
       Uр
sum(diag(tab))/sum(tab)
## [1] 0.5865385
```

For KNN, we need to remember that the syntax is slightly different in that the training and the testing are immediately input into the command.

```
## Down 21 30

## Up 22 31

sum(diag(tab))/sum(tab)

## [1] 0.5
```

The logistic regression and the LDA - despite being the simplest - perform the best.

For the remainder of the project, solutions will vary.
