1. Is at least one of the predictors  $X_1, X_2, ..., X_p$  useful in predicting the response?

- 1. Is at least one of the predictors  $X_1, X_2, ..., X_p$  useful in predicting the response?
- 2. Do all the predictors help to explain Y, or is only a subset of the predictors useful?

- 1. Is at least one of the predictors  $X_1, X_2, ..., X_p$  useful in predicting the response?
- 2. Do all the predictors help to explain Y, or is only a subset of the predictors useful?
- 3. How well does the model fit the data?

- 1. Is at least one of the predictors  $X_1, X_2, ..., X_p$  useful in predicting the response?
- 2. Do all the predictors help to explain Y, or is only a subset of the predictors useful?
- 3. How well does the model fit the data?
- 4. Given a set of predictor values, what response value should we predict, and how accurate is our prediction?

## Is at least one predictor useful?

For the first question, we can use the F-statistic

$$F = \frac{(TSS - RSS)/p}{RSS/(n-p-1)} \sim F_{p,n-p-1}$$

Quantity	Value
Residual Standard Error	1.69
$R^2$	0.897
F-statistic	570

# Deciding on the important variables

• The most direct approach is called *all subsets* or *best subsets* regression: we compute the least squares fit for all possible subsets and then choose between them based on some criterion that balances training error with model size.

# Deciding on the important variables

- The most direct approach is called *all subsets* or *best subsets* regression: we compute the least squares fit for all possible subsets and then choose between them based on some criterion that balances training error with model size.
- However we often can't examine all possible models, since they are 2<sup>p</sup> of them; for example when p = 40 there are over a billion models!
  Instead we need an automated approach that searches through a subset of them. We discuss two commonly use approaches next.

#### Forward selection

- Begin with the *null model* a model that contains an intercept but no predictors.
- Fit p simple linear regressions and add to the null model the variable that results in the lowest RSS.
- Add to that model the variable that results in the lowest RSS amongst all two-variable models.
- Continue until some stopping rule is satisfied, for example when all remaining variables have a p-value above some threshold.

### Backward selection

- Start with all variables in the model.
- Remove the variable with the largest p-value that is, the variable that is the least statistically significant.
- The new (p-1)-variable model is fit, and the variable with the largest p-value is removed.
- Continue until a stopping rule is reached. For instance, we may stop when all remaining variables have a significant p-value defined by some significance threshold.

#### Model selection — continued

- Later we discuss more systematic criteria for choosing an "optimal" member in the path of models produced by forward or backward stepwise selection.
- These include Mallow's  $C_p$ , Akaike information criterion (AIC), Bayesian information criterion (BIC), adjusted  $R^2$  and Cross-validation (CV).
