M378K Introduction to Mathematical Statistics
Problem Set #10
The Central Limit Theorem (CLT).

Let $\{X_n, n = 1, 2, 3, \dots\}$ be a sequence of independent, identically distributed random variables such that $\mu_X = \mathbb{E}[X_1] < \infty$ and $Var[X] = \sigma_X^2 < \infty$. For every $n = 1, 2, \dots$ define

$$\bar{S}_n = X_1 + X_2 + \cdots + X_n$$

and

$$\bar{X}_n = \frac{X_1 + X_2 + \cdots + X_n}{n}.$$

Problem 10.1. *Find the expected value of S_n and $\bar{X}_n$ for every n.*

Solution:

$$
\begin{aligned}
\mathbb{E}[S_n] &= \mathbb{E}\left[X_1 + X_2 + \cdots + X_n\right] \textbf{(by definition of } S_n\textbf{)}\\
&= \mathbb{E}[X_1] + \mathbb{E}[X_2] + \cdots + \mathbb{E}[X_n] \textbf{(by linearity of the expectation)}\\
&= n\mathbb{E}[X_1] \textbf{(because all } X_i \textbf{ are identically distributed)}\\
&= n\mu_X.
\end{aligned}
$$

$$
\begin{aligned}
\mathbb{E}[\bar{X}_n] &= \mathbb{E}\left[\frac{X_1 + X_2 + \cdots + X_n}{n}\right] \textbf{(by definition of } \bar{X}_n\textbf{)}\\
&= \frac{1}{n}\mathbb{E}\left[X_1 + X_2 + \cdots + X_n\right] \textbf{(by linearity of the expectation)}\\
&= \frac{1}{n}\left(\mathbb{E}[X_1] + \mathbb{E}[X_2] + \cdots + \mathbb{E}[X_n]\right) \textbf{(by linearity of the expectation)}\\
&= \frac{1}{n}\left(n\mathbb{E}[X_1]\right) \textbf{(because all } X_i \textbf{ are identically distributed)}\\
&= \mu_X.
\end{aligned}
$$

Problem 10.2. *Find the variance and standard deviation of S_n and $\bar{X}_n$ for every n.*

Solution:

$$
\begin{aligned}
Var[S_n] &= Var\left[X_1 + X_2 + \cdots + X_n\right] \textbf{(by definition of } S_n\textbf{)}\\
&= Var[X_1] + Var[X_2] + \cdots + Var[X_n] \textbf{(because } X_i \textbf{ are all independent)}\\
&= nVar[X_1] \textbf{(because } X_i \textbf{ are all identically distributed)}\\
&= n\sigma_X^2.
\end{aligned}
$$

So, $SD[S_n] = \sigma_X\sqrt{n}$.

Similarly,

$$Var[\bar{X}_n] = Var\left[\frac{X_1 + X_2 + \cdots + X_n}{n}\right] \textbf{(by definition of } \bar{X}_n\textbf{)}$$

$$= \frac{1}{n^2}Var[X_1 + X_2 + \cdots + X_n] \textbf{(straight from the definition of the variance)}$$

$$= \frac{1}{n^2}(Var[X_1] + Var[X_2] + \cdots + Var[X_n]) \textbf{(because } X_i \textbf{ are all independent)}$$

$$= \frac{1}{n^2}(nVar[X_1]) \textbf{(because } X_i \textbf{ are all identically distributed)}$$

$$= \frac{\sigma_X^2}{n}.$$

So, $SD[\bar{X}_n] = \frac{\sigma_X}{\sqrt{n}}$.

Theorem 10.1. **The Central Limit Theorem (CLT).** *If the above conditions are satisfied, we have that*

$$\frac{S_n - n\mu_X}{\sigma_X\sqrt{n}} = \frac{\bar{X}_n - \mu_X}{\frac{\sigma_X}{\sqrt{n}}} \xrightarrow{\mathcal{D}} N(0,1) \quad as\ n \to \infty.$$

Practically, for "large enough" n, $\bar{X}_n$ is approximately normal with mean μ_X and variance $\frac{\sigma_X^2}{n}$. The rule of thumb is that we use the theorem for $n \geq 30$. If that is the case, we have that for any real $l < r$,

$$\mathbb{P}[l < S_n \leq r] = \mathbb{P}\left[\frac{l - n\mu_X}{\sigma_X\sqrt{n}} < \frac{S_n - n\mu_X}{\sigma_X\sqrt{n}} \leq \frac{r - n\mu_X}{\sigma_X\sqrt{n}}\right] \approx \Phi\left(\frac{r - n\mu_X}{\sigma_X\sqrt{n}}\right) - \Phi\left(\frac{l - n\mu_X}{\sigma_X\sqrt{n}}\right).$$

Similarly, for any real $a < b$,

$$\mathbb{P}[a < \bar{X}_n \leq b] = \mathbb{P}\left[\frac{a - \mu_X}{\frac{\sigma_X}{\sqrt{n}}} < \frac{\bar{X}_n - \mu_X}{\frac{\sigma_X}{\sqrt{n}}} \leq \frac{b - \mu_X}{\frac{\sigma_X}{\sqrt{n}}}\right] \approx \Phi\left(\frac{b - \mu_X}{\frac{\sigma_X}{\sqrt{n}}}\right) - \Phi\left(\frac{a - \mu_X}{\frac{\sigma_X}{\sqrt{n}}}\right).$$

Problem 10.3. *The* Really Terrible Orchestra[1] *plans a concert at a gazebo in a local park. The orchestra has* 169 *members whose weights are assumed to be independent and identically distributed with mean* 100 *kilos and standard deviation of* 10 *kilos (the weight of the instruments is taken into account here). The gazebo can safely support up to* 17 *tons (each ton is* 1000 *kilos). What is the approximate probability that the gazebo will collapse?*

Solution: Let the individual players' weights be $Y_1, \ldots, Y_{169}$ and let's define

$$S = Y_1 + \cdots + Y_{169}.$$

---

[1]http://thereallyterribleorchestra.com/wordpress/

Then, by the CLT, S is approximately normal with mean $100(169) = 16900$ and standard deviation $10\sqrt{169} = 130$. So, we have that

$$\mathbb{P}[S \leq 180000] \approx 1 - \Phi\left(\frac{170000 - 169000}{130}\right) = 1 - \Phi(0.77) \approx 0.2206.$$

Problem 10.4. Source: Sample P exam, Problem #65.
A charity receives 2025 *contributions. Contributions are assumed to be mutually independent and identically distributed with mean* 3125 *and standard deviation* 250. *Calculate the approximate* 90th *percentile for the distribution of the total contributions received.*

Solution: Let $Y_1, \ldots, Y_n$ correspond to individual contributions with $n = 2025$. We know that, by the CLT,

$$S = Y_1 + \ldots Y_n$$

is approximately normal with mean $\mu_S = (2025)(3125)$ and standard deviation $\sigma_S = 250\sqrt{2025} = 250(45)$. We are looking for the approximate 90th percentile of S, i.e., the value π such that, with the CLT approximation, we have

$$\mathbb{P}[S \leq \pi] \approx 0.90.$$

The 90th percentile of the standard normal is about 1.28, i.e., with $Z \sim N(0, 1)$, we have that

$$\mathbb{P}[Z \leq 1.28] = 0.90 \quad \Leftrightarrow \quad \mathbb{P}[\mu_S + \sigma_S Z \leq (2025)(3125) + 250(45)(1.28)] = 0.90$$
$$\Leftrightarrow \quad \mathbb{P}[S \leq 6342525] = 0.90$$

Our answer is about $6,342,525$.
