39. You are given a dataset with two variables, which is graphed below. You want to predict y using x.

Determine which statement regarding using a generalized linear model (GLM) or a random forest is true.

X (A) A random forest is appropriate because the dataset contains only quantitative variables. Trees in general work well w/ qualitative predictors.

X (B) A random forest is appropriate because the data does not follow a straight line. The opposite is true.

X (C) A GLM is not appropriate because the variance of y given x is not constant. The variance looks pretty constant

X (D) A random forest is appropriate because there is a clear relationship between y and x. Could be any relationship!

(E) A GLM is appropriate because it can accommodate polynomial relationships.
